

# The Role of Scripting and Automation in Modern Cloud Operations

University of Essex Online  
Tobias Zeier, 20 August 2025

---

Automation through scripting is a foundational practice in modern cloud computing, significantly enhancing operational efficiency, consistency, and scalability. This approach, exemplified by the provided *provision.sh* script, allows for the repeatable and reliable deployment of cloud infrastructure, mitigating the risks associated with manual processes. Scripting transforms complex, multi-step procedures into a single, automated workflow, thereby reducing human error and freeing up personnel to focus on more strategic initiatives.<sup>1</sup> This aligns with contemporary Site Reliability Engineering (SRE) principles, which advocate for the automation of routine tasks to improve system reliability and reduce downtime (Dave, 2023).

## The Role of Infrastructure as Code

The *provision.sh* script serves as a practical example of Infrastructure as Code (IaC), a paradigm where infrastructure is managed and provisioned using code rather than through manual configuration (Nuti, 2025). This method ensures that the infrastructure environment is version-controlled, testable, and reusable. For instance, the script's core commands are designed to be idempotent, meaning they can be run multiple times without causing unintended side effects. The script checks for the existence of networks, security groups, and images before creating them, ensuring a consistent and predictable state with every execution. This addresses a key challenge in large-scale cloud environments, where maintaining operational consistency is paramount to preventing misconfigurations and ensuring system stability (Koneru, 2025).

## Efficiency, Scalability, and Consistency

The primary benefit of cloud automation is the dramatic increase in operational speed and efficiency. Manually configuring cloud resources is a time-consuming and error-prone process. By automating these tasks, the time to deploy new environments or scale existing ones is reduced from hours to mere minutes (Madamanchi, 2025). The *provision.sh* script showcases this by automating the

entire lifecycle of a virtual instance, from network setup to floating IP assignment. The script's manual polling loop to wait for the instance to become 'active' is a robust automation pattern that eliminates manual checks and retries.

This automation also facilitates unprecedented scalability. When an organisation's demands increase, scripts can be readily adapted to provision hundreds or thousands of instances on demand. The logic in the *provision.sh* script to check for and reuse an unassigned floating IP address highlights another key aspect of smart automation: resource optimisation. By automating the management of these resources, an organisation can avoid unnecessary costs associated with creating new floating IPs when existing ones are available. This demonstrates how scripting can lead to significant cost savings and more sustainable cloud usage (Nuti, 2025). In essence, the move towards scripting in cloud operations is a strategic shift from manual, reactive management to a proactive, codified approach. The provided script, although simple in its structure, embodies the core tenets of modern DevOps and cloud engineering: it prioritises automation to achieve greater speed, maintain a consistent state, and enable scalable, cost-effective infrastructure management (Dave, 2023).
